Preparation

ABSTRACT

Background: Medical problems are prevalent among young travellers. A quasi-experimental study was conducted to investigate the impact of country-specific pre-departure preparation in the occurrence of medical and psychological problems among Australian gap year.

Methods: Participants were recruited during two periods, 2013-14 and 2017-18 from an organisation that specialises in gap year placements. Based on results of our previous study of the 2013-14 cohort, improvements in the pre-departure preparation were introduced. Demographic, placement, and pre-departure preparation characteristics as well as psychological stressors, coping mechanisms, and medical problems were collected and compared between the two cohorts.

Results: Demographic and placement characteristics were similar between the two cohorts. There was a significant increase in the proportion of travellers that read the briefing material (from 80% to 100%; p-value < 0.001), carried a first aid kit (from 26% to 62%; p-value < 0.001), and accessed information on how to deal with common health problems (from 46% to 61%; p-value = 0.047). All psychological stressors decreased, except for feeling home sick that remained high (72%). Medical problems remained prevalent; half of the gap year travellers sought medical attention, yet there was a significant reduction in sunburn (from 59% to 37%; p-value = 0.040), diarrhoea/food poisoning (from 44% to 21%; p-value = 0.015), weight change (from 41% to 16%; p-value = 0.006), and skin infections (from 38% to 9%; p-value < 0.001).

Conclusions: Gap year travellers are exposed to a wide range of health risks and experience higher proportion of medical problems than standard tourists. A comprehensive country-specific pre-departure preparation had a positive impact on the gap year travellers' wellbeing.

1. Introduction

Over the last decade increasing numbers of young adults are travelling overseas for extended periods after the completion of high school. This "gap year" is typically taken prior to commencing tertiary education or employment. Commercial and not-for-profit organisations facilitate opportunities for participants to undertake volunteer work in developing countries, where they can potentially be exposed to a wide range of health risks (e.g. travel-related infectious diseases, injuries, accidents) in locations where medical infrastructure may be poor. Medical problems are common among gap year travellers [1-4] and these problems may persist after returning home [2,5]. Medical problems may differ across age groups as young travellers are more likely to have risk-taking attitudes [6] and engage in high-risk activities than older travellers.

In our initial study, using data from a 2013-14 cohort of young Australian gap year travellers, we found high prevalence of psychological stressors as well as medical problems that may have been preventable (e.g. sunburn) [1]. Findings from the initial study were reported to the organisation that coordinated the gap year placements. As a result, changes in the pre-departure procedures and on-site support were instigated. Among the most significant changes implemented by the organisation were the introduction of a compulsory country-specific briefing session and a support plan for use in-country for all gap year travellers who had health conditions noted during the pre-departure medical screening. We therefore conducted a follow-up study on a 2017-18 cohort of gap year travellers to investigate changes in the health problems and coping mechanisms they used during their placement as well as to contrast the findings with the 2013-14 cohort of gap year travellers.

2. Materials and methods

2.1. Study setting and participants

A quasi-experimental study was conducted to assess the effectiveness of the interventions put in place to reduce medical problems and better manage psychological stressors. Gap year travellers from Lattitude Global Volunteering (www.lattitude.org.au), an international youth development non-profit organisation that specialises in gap year placements, were invited to participate in the study. Participants were recruited in Australia during the periods of December 2013 to April 2014 (i.e. 2013-14 cohort) [1] and November 2017 to June 2018 (i.e. 2017-18 cohort).

The same data collection procedures were used for both cohorts, i.e. two online self-administered questionnaires using Qualtrics (www.qualtrics.com), a secure cloud-based data collection and management system. A web-link with the pre-travel questionnaire was sent by Lattitude Global Volunteering to the gap year travellers to obtain demographic data, previous travel experience, placement destination and duration, and pre-departure preparation. Upon return from their placement, a web-link with the post-travel questionnaire was sent to collect information about their experiences overseas, issues around health and wellbeing, and challenges encountered. Two reminders were sent two weeks apart to the gap year travellers who did not respond to the online questionnaires.

The study received the approval of the Human Research Ethics Committee of the Australian National University (2019/460). All the participants provided written informed consent.

2.2. Changes in the pre-departure preparation and on-site support

In 2013–14, before departure, all gap year travellers underwent medical screening by a Medical Advisor. All gap year travellers were invited to a face-to-face generic pre-travel briefing session that covered culture shock, safety and security, practical preparation, and common challenges. If the gap year traveller could not attend the briefing, the material was posted to them to read. Whilst on placement, gap year travellers attended an orientation on arrival and had a dedicated mentor at their placement to support them with day-to-day issues. Gap year travellers were also visited by Lattitude Global Volunteering staff to check on their progress and they had access to a 24/7 emergency number manned by experienced staff from Lattitude Global Volunteering in Australia.

In 2017–18, the compulsory medical screening remained unchanged. The generic face-to-face briefing session was replaced by online compulsory country-specific briefing sessions. If the gap year traveller could not join to the online briefing session, a link of the recording was sent to them. In these sessions the gap year travellers received 1) an overview of the program in their country of placement (e.g. general country information, a typical day at placement, where the placements are located, accommodation); 2) pre-departure essential actions (e.g. visas, passports, medications, vaccines); 3) in-depth country-specific health, safety, and security information; including an electronic version of the book “Travelling Well: The ‘Must Have’ Guide to a Safe and Healthy Journey” [7] and the smartphone app Travel Health Guide [8]; and 4) how to access ladder of support (i.e. first contact placement host, then country manager followed by the coordinator in Australia). During the online briefing sessions, the gap year travellers also saw videos detailing the experiences from returned gap year travellers about key challenges in that country, first impressions, culture shock, reverse culture shock, and communication issues. Gap year travellers also received information regarding post-placement travel (e.g. extending visas, returning home). Lattitude Global Volunteering verified that the gap year travellers understood the information provided in the briefing sessions and read the briefing material, thus an online assessment was introduced, and the gap year

travellers had to pass each assessment to continue and complete the pre-departure training.

Another change was the instigation of mandatory and customised support plans for all gap year travellers with identified pre-existing health conditions (e.g. asthma) in case they needed support during their placement. A Medical Advisor examined the gap year travellers, reviewed their medical records and provided a detailed plan of action (medications and recommendations) should the condition deteriorate while on placement. These gap year travellers also received regular follow-ups by country managers.

2.3. Statistical analysis

The dataset was de-identified before statistical analysis. Chi-squared test and *t*-test were used to compare categorical and numerical variables between the 2013-14 and 2017-18 cohorts. All the analyses were conducted in Stata MP 14 (StataCorp, College Station, TX, USA).

3. Results

In 2013-14 and 2017–18, 88 (out of 185) and 86 (out of 104) gap year travellers agreed to participate and completed the pre-travel questionnaire, respectively. Demographics, financial responsibilities, and placement characteristics were similar between the 2013-14 and 2017-18 cohorts. The only difference observed was in the continent of placement; in 2017-18 a higher proportion of gap year travellers were placed in Europe and North America (from 51.1% to 76.7%), while the proportion of gap year travellers to Asia decreased compared to 2013–14 (from 28.4% to 11.6%). However, the difference in placement destination (tropical versus non-tropical [*p*-value = 0.721] or high income versus mid/low income [*p*-value = 0.773]) were not associated with the need to seek medical attention by the gap year travellers. There was an increase in the proportion of gap year travellers reporting previous experience in the type of work assigned during the placement (from 22.7% to 34.9%), but this was not statistically significant (Table 1).

Pre-departure preparation improved between the study periods. In 2017–18, 100% of gap year travellers reported reading the briefing material provided by Lattitude Global Volunteering as compared to 80.7% in 2013–14. There was a significant increase in the proportion of gap year travellers carrying first aid kits (from 26.1% to 61.6%), as well as accessing information on how to deal with common health problems (e.g. Dr Deb's Travelling Well book) (from 45.5% to 60.5%). The proportion of gap year travellers that contacted previous gap year participants before their placement decreased by 15.8%. The proportion of gap year travellers attending a specialised travel medicine clinic prior to their placement remained low at 30.2% (Table 1).

The response rate for post-travel questionnaires improved from 38.6% in 2013-14 to 77.9% in 2017–18. The proportion of gap year travellers that engaged in outdoor activities and risky behaviours was similar between cohorts, except for bungee jumping and/or skydiving which was higher in 2017–18. The latter cohort travelled less within the country of their placement (Table 2).

In terms of psychological stressors, feeling homesick remained the main problem faced by gap year travellers. Nearly three-quarters of them reported feeling homesick at some stage during their placement. There was a significant decrease in all other psychological stressors (i.e. culture shock, difficulty communicating, and difficulty with the work assigned). Sixty-two (92.5%) of the gap year travellers in the 2017-18 cohort reported that the coping techniques they used were effective. Between the two cohorts, coping mechanisms employed by the gap year travellers shifted from “mainly trying to work out a solution by themselves” to “communicating with others” and “seeking advice” (e.g. call home to talk to friends/family) (Table 3). Some of the explanations provided by the gap year travellers explaining why their coping mechanism worked were:

findings. \
